

HACKFOLIO

Comprehensive User Manual & Workflow Document

Version: 1.0.0

Date: May 12, 2026

Status: Official Documentation

Executive Summary

Hackfolio is a state-of-the-art platform designed for developers and hackers to showcase their projects and hackathon entries in a visually stunning and organized manner. By providing a drag-and-drop portfolio builder, Hackfolio simplifies the process of creating professional-grade project showcases without requiring deep frontend expertise for every individual project.

1. User Manual

1.1 Authentication

Users can register and log in to Hackfolio using their email and password. Secure JWT-based authentication ensures that user data and projects remain private and protected.

1.2 Dashboard

The Dashboard is the central hub where users can view all their projects, monitor their performance (view counts), and initiate the creation of new portfolios.

1.3 Portfolio Builder

The Builder provides a dynamic workspace where users can add sections, customize text, and upload images. Key features include:

- **Drag-and-Drop:** Reorder sections with ease.
- **Real-time Preview:** See changes as you make them.
- **Rich Content:** Add taglines, project descriptions, and technical stacks.

1.4 Publishing

Once a portfolio is ready, users can publish it to generate a unique public URL (slug). These public pages are optimized for speed and SEO, making them perfect for sharing with recruiters or on social media.

2. Technical Workflow

2.1 System Architecture

The system follows a modern decoupled architecture consisting of a robust backend API and a high-performance frontend application.

Component	Technology Stack	Responsibility
Frontend	React, Tailwind, Zustand	User Interface, Builder Logic, Routing
Backend	Node.js, Express, TypeScript	API, Business Logic, Security
Database	Supabase (PostgreSQL)	Data Persistence, Storage
Auth	JWT / Supabase Auth	User Security & Session Management

2.2 Data Flow

The application follows a strict data flow pattern to ensure maintainability:

- Client Request:** The React frontend makes an authenticated request via Axios/React Query.
- Route Handler:** Backend Express routes capture the request and pass it to controllers.
- Use Case:** Controllers invoke specific business logic (Use Cases) that implement project requirements.
- Infrastructure:** Repositories interact with Supabase to fetch or persist data.

2.3 API Endpoints

Method	Endpoint	Description
POST	/api/auth/signup	Register a new user
POST	/api/auth/login	Authenticate user
GET	/api/projects	Fetch user projects
POST	/api/projects	Create new project
GET	/api/p/:slug	Public project view
POST	/api/upload	Asset management

3. Setup & Installation

3.1 Prerequisites

- Node.js (v18 or higher)
- PNPM (recommended package manager)
- Supabase Account & Project

3.2 Environment Configuration

Both backend and frontend require .env files containing API keys, database URLs, and port configurations. Refer to .env.example files in respective directories for details.

3.3 Running Locally

Backend: npm run dev

Frontend: npm run start
